

Breathing Room

The Inside

Application of Breathing System

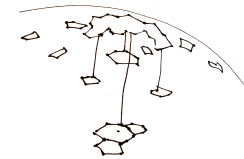

From within, the **Breathing Room** consists of a sonar sensor at it's suspended heart to detect micro-movements that light up a hexagonal constellation of light- this means that with no forced interaction whatsoever, a human will be completely in sync with the dramatic light within.

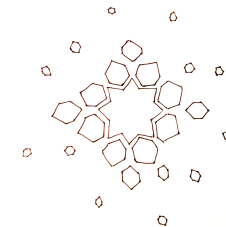

Micro movements imply that if the individual is calm - breath alone will control the light. So standing or supine, the lights rise and dim with the user- reflective of the life force within.

The lights above the individual are three dimensionally arranged in a hexa-architectural pattern mimicing the form of the dome within which it us housed, allowing for a sense of singular one-ness with the plant body.

We have developed this using sonar sensors and extensively tested the system to create a robust, plug and play, entirely original application that can be powered by solar energy alone.
